

# Medical Physics Module Semester 1

**Session 5**  
**Lecture 10**

## *Physics of eyes and vision*

**By: Lect. Dr. Nadia Hussein Sahib**

# Objectives

- Physical principle of vision.
- The effect of diffraction of light in the process of vision.
- How eyes focus on object ?
- Physics of different focusing diseases & their correction.

## Obj.1 Physical principle of vision.

The eye is an optical instrument that can focus automatically on objects over a wide range of distances.

➤ To view a near object, the eye muscles must become tight so that the muscle fibers shorten and make the eye lens thicker and more powerful.

➤ To view a distant object, the eye muscles must relax so that the muscle fibers lengthen, allowing the eye lens to become thin and less powerful.

## Sensitivity of the eye consists of three major components:

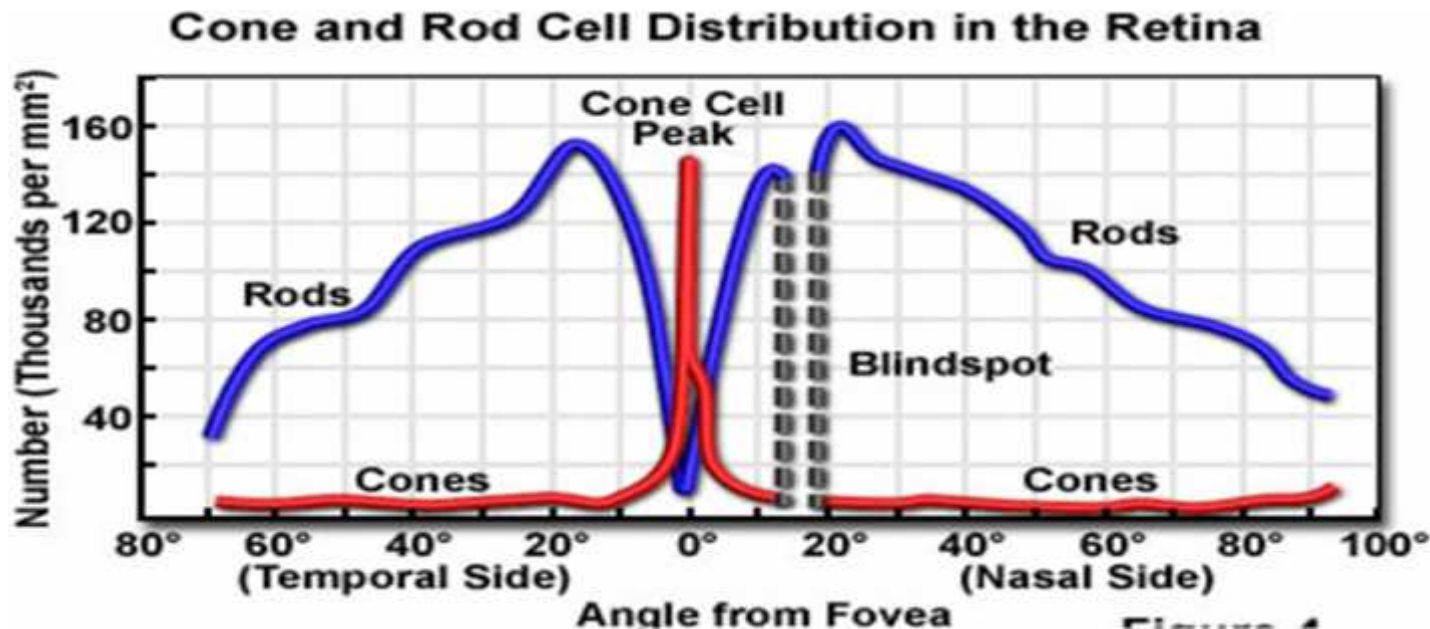

1. Rods are sensitive to low levels of light intensity but cannot distinguish between colors.

2. Cons are of three types, each sensitive to a different range of wavelengths.

These ranges correspond broadly to red, green or blue light. The system of millions of nerves that carries information deep into the brain.

### 3. Visual acuity, the minimum angular separation of the two equidistance points of light which can just be resolved by the eye.

Absorption Spectra of Human Visual Pigments

## Retina is the light detector of eye

Retina the light sensitive part of eyes, converts the light images into electrical nerve impulses that are sent to the brain. The photon must be above minimum energy to cause the reaction.

- **Infrared photons have insufficient energy and are not seen.**
- **Ultraviolet photons have sufficient energy but they are absorbed before they reach the retina and also are not seen.**

## Obj.2 Diffraction effects on the eye

All light waves undergo diffraction when it passes through small openings thus the iris produces diffraction pattern on the retina. All lenses have defects aberration. The effect of such aberration is reduced if the lenses opening are made smaller. A point source of light will not be focused on single cone because of diffraction effects.

The angular spread ( $2\theta$ ) of the central bright spot at retina for ( $\lambda = 555 \text{ m}$ ) and pupil (3 mm) diameter ( $a$ ) is given by:

$$2\theta = 2(1.22) \lambda / a$$

$$2(1.22) (555 \times 10^{-9} / 3 \times 10^{-3}) = 4.5 \times 10^{-4} \text{ radians}$$

## Obj.3

# Focusing elements of the eye

The eye has two major focusing components:

1. The cornea which is clear transparent bump on the front of the eye. the cornea is fixed focus element.
2. The lens is variable in shape and has ability to focus at various distances.

- The cornea focus by bending (refraction) the light rays, the amount of bending depends on the curvature and speed of the light in lens.
- When cornea under ware it losses most of its focusing power because the index of refraction of water (1.33) close to that of cornea (1.37).

# Structure of the Human Eye

## Cornea

protects eye  
refracts light

## Iris

colored muscle  
regulates pupil size

## Pupil

regulates light input

## Lens

focuses images on retina

## Ciliary Muscles

controls shape of lens  
accommodation

## Fovea

point of central focus  
contains most cones  
birds of prey/rodent variation

## Retina

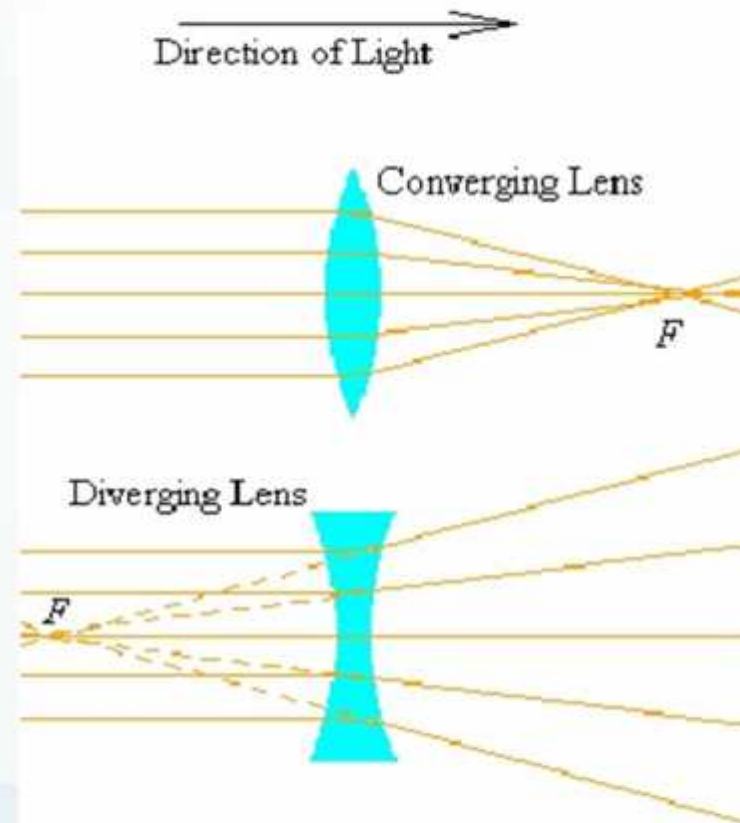

contains photoreceptors

# Convergent & Divergent Lenses

- Convex lenses refract light in a towards each other: **convergent**
- Concave lenses refract parallel light rays away from each other: **divergent**

Light that travels through the center of either lens continues straight through and is NOT refracted.

## Defective vision & its correction

### Converging and diverging lenses:

- A converging lens makes parallel rays converge to a focus.
- A diverging lens makes parallel rays diverge (spread out).

$$\mathbf{1/F = 1/U + 1/V}$$

**F = focal length**

**U = object distance**

**V = image distance (F)**

## Obj.4 Some diseases of refractive errors of vision

<b>Focusing problem</b>	<b>Common name</b>	<b>Usual cause</b>	<b>Correction</b>
<b>Myopia</b>	<b>Near sighted vision</b>	<b>Long eye ball or cornea too curved</b>	<b>Negative lens or cornea too curved</b>
<b>Hyperopic</b>	<b>Far sighted vision</b>	<b>Short eye ball or cornea not curved Enough</b>	<b>Positive lens</b>
<b>Astigmatism</b>		<b>Unequal curvature of cornea</b>	<b>Cylindrical lens</b>
<b>Presbyopia</b>	<b>Old age vision</b>	<b>Lack of accommodation</b>	<b>Bifocals</b>

## Vision Problem: Myopia

A nearsighted (myopic) eye focuses the light rays to a point **in front** of the retina.

Myopia can be corrected with **diverging** lenses.

Hyperopic Eye

Hyperopic Eye + a positive lens

## **Healthy eye**

## **Astigmatism**
